**Abstract:** *Sex is at the very core of individual identity. It affects the conception of self and the way others view the individual. Every day, one's sex may open and close doors, access to communities, and opportunities. Laws that define sex may affirm scientific knowledge and protect people or threaten to unravel the facts and the reality of sex. A deep unmooring of sex is underway, and this article aims to stop it. On day one of the current presidential term, January 20, 2025, President Trump signed an Executive Order on "Defending Women from Gender Ideology Extremism and Restoring Biological Truth to the Federal Government." The Executive Order seeks to define sex to stop a problem it characterizes as follows: "Across the country, ideologues who deny the biological reality of sex have increasingly used legal and other socially coercive means to permit men to self-identify as women and gain access to intimate single-sex spaces and activities designed for women, from women's domestic abuse shelters to women's workplace showers." The Executive Order follows laws in multiple states that have restricted access to women's and girls' sports, restricted access to bathrooms, and prohibited or restricted access to gender affirming care.*

*This article takes seriously the assertion that there is a biological reality of sex. By examining the scientific and medical evidence this article demonstrates that sex determination does not and cannot occur at fertilization but is instead a complex process occurring at various stages of human development from the embryonic and fetal stage through adulthood. Ultimately, with this complexity as a guiding frame, this article concludes that legal definitions and related laws must align to the evidence and the lived experience of individuals.*

## Introduction

On January 20, 2025, President Trump signed an Executive Order on “Defending Women from Gender Ideology Extremism and Restoring Biological Truth to the Federal Government” (EO). Among the stated purposes of the EO are to combat “Efforts to eradicate the biological reality of sex fundamentally attack women by depriving them of their dignity, safety, and well-being.” The goal is to rest these decisions on scientific and medical truth. “Basing

Federal policy on truth is critical to scientific inquiry, public safety, morale, and trust in government itself.” This article takes this task seriously by examining the scientific and medical evidence to construct a legal definition based on the biological reality of sex.

The EO seeks to use “clear and accurate language and policies that recognize women are biologically female, and men are biologically male.” The EO also provides these “clear and accurate” definitions. In defining sex the EO states, “‘Sex’ shall refer to an individual’s immutable biological classification as either male or female.” The EO also establishes what it excludes from the definition of sex, “‘Sex’ is not a synonym for and does not include the concept of ‘gender identity.’” The EO defines the gender categories of Women/Woman/Girls/Girl through the sex category of “adult and juvenile human females, respectively.” The same for Men/Man/Boys/Boy which “shall mean adult and juvenile human males, respectively.”

Determination of sex is made at “conception” by the size of the “reproductive cell.” Under this standard, “‘Female’ means a person belonging, at conception, to the sex that produces the large reproductive cell” and “‘Male’ means a person belonging, at conception, to the sex that produces the small reproductive cell.”

The EO raises many questions, among these are whether these definitions represent the “biological reality of sex,” whether this policy is based on “truth,” whether it is based on “scientific inquiry,” whether these definitions are “clear and accurate,” whether male and female are “immutable biological classifications,” whether sex is “synonymous” with or includes “gender identity,” whether sex determination can or should be made at “conception,” and whether female is “the sex that produces the large reproductive cell” and male is “the sex that produces the small reproductive cell.” Also important is to determine if these definitions and processes of sex testing stop the “fundamental[ ] attack [on] women [that is] depriving them of their dignity, safety, and well-being.” In other words, does the “truth” of these definitions advance, “scientific inquiry, public safety, morale, and trust in government itself.”

This article will explore these questions by examining when and how sex testing occurs and whether these standards align with the “biological reality of sex.”

## **I. The Biological Reality of Sex Before Birth and the Process of Sex Differentiation and Determination**

The Executive Order on “Defending Women from Gender Ideology Extremism and Restoring Biological Truth to the Federal Government” attempts to restore biological truth and “biological reality of sex.” The EO alleges that this truth is established at

conception and differentiates Male and Female based on the size of the reproductive cell: “‘Female’ means a person belonging, at conception, to the sex that produces the large reproductive cell” and “‘Male’ means a person belonging, at conception, to the sex that produces the small reproductive cell.” These definitions are not biological truth and do not reflect the biological reality of sex at fertilization.

Medical doctors and scientists do not use the term conception because it is not a scientific term. Instead, scientific literature uses the term fertilization. “The chromosomal sex of an embryo is established at fertilization” but this is not the biological reality of sex.<sup>1</sup> There is no known test of chromosomal sex that can be conducted at fertilization in humans during pregnancy. The reality is that the “first signs of sex differentiation are noticed” in humans 6 weeks after fertilization.<sup>2</sup> Prior to this stage human gonads are sexually indifferent.<sup>3</sup> Measuring the size of the reproductive cells at this stage of development does not differentiate sex. The process of sex determination and differentiation involves “[a] bewildering number of hormones and growth factors.”<sup>4</sup>

Prior to the sixth week of embryonic development in humans, “no sexual difference can be observed in the gonads.”<sup>5</sup> Thus, differentiation between the large and small reproductive cell is not possible at fertilization. During the first six weeks, the “[u]ndifferentiated gonads of XX or XY individuals are apparently identical and can form either ovaries or testes.”<sup>6</sup> The development of the gonadal ridge is the first time sex can be differentiated, but sex differentiation at this stage is not immutable. During the development of the gonadal ridge, adrenal agenesis can occur and

“subsequent gonadal degeneration and XY sex reversal.”<sup>7</sup> In general sex reversal is more common in XY embryos.<sup>8</sup>

Starting with the work of Alfred Jost in the 1940’s the existence of testes has been identified as differentiating “the sexually dimorphic fate of the internal and external genitalia.”<sup>9</sup> The existence of testes “irrespective of their chromosomal constitution . . . [result in] all internal and external genitalia develop[ing] following the male pathway.”<sup>10</sup> A lack of testes results in genitalia developing “along the female pathway.”<sup>11</sup> On the other hand, “The existence of ovaries has no effect on fetal differentiation of the genitalia.”<sup>12</sup> The process for adequate testes differentiation and secretion of masculinizing hormones involves a myriad of vascular, cellular, and molecular pathways that must occur in a specific sequence, at certain levels, and in a narrow time period in embryonic and fetal development.<sup>13</sup> The genetic pathway to ovarian differentiation and stabilization, although it does not impact fetal differentiation, also involves a complex process of cell pathways.<sup>14</sup>

The internal reproductive tract is similar in both sexes until the eighth week of embryonic development.<sup>15</sup> Only between the ninth and thirteenth week of embryonic development does the upper

part of the internal reproductive tract start to differentiate.<sup>16</sup> Until approximately the ninth week of embryonic development external genitalia is undifferentiated.<sup>17</sup> The masculinization of external genitalia is marked by prostatic development and repression of vaginal development.<sup>18</sup> Despite higher testosterone levels that peak between weeks eleven to fourteen in embryonic development, no size difference exists between penile or clitoral size until fourteen weeks of embryonic development.<sup>19</sup> In fact, testosterone levels may not impact phallic growth as, “Maximal phallic growth occurs during the third trimester of fetal life, at a time when male testosterone levels are declining.”<sup>20</sup> The vaginal rudiment does not open up until the twenty-second week of embryonic development.<sup>21</sup> Development of the “Early patterning of external genitalia is regulated by a cascade of signaling molecules.”<sup>22</sup> Development along the female pathway is the default pattern in embryonic development, “the reproductive tract, whatever its genetic sex, will develop along female lines provided it is not exposed to testicular hormones, the main forces driving male sex differentiation.”<sup>23</sup>

The most common form of sex identification before birth is an ultrasound in the second or third trimester.<sup>24</sup> Accuracy during

these stages of pregnancy is more than 99%.<sup>25</sup> Accuracy is measured based on an actual determination and excludes instances where no determination is made or there is ambiguity. First trimester sex identification is less common and normally used to monitor risk of sex-linked disorders.<sup>26</sup> First trimester sex identification starting at twelve weeks is increasing in accuracy, but gestational age still improves accuracy.<sup>27</sup> Earlier testing is possible using chorionic villus sampling from eleven weeks or amniocentesis from fifteen weeks to identify the presence of a Y chromosome for sex linked genetic diagnosis, “but both techniques carry a small but significant miscarriage risk.”<sup>28</sup> The presence of a Y chromosome using non-invasive prenatal diagnosis (NIPD) can now be performed using cell-free fetal DNA in maternal plasma at 7 weeks with high accuracy.<sup>29</sup> The EO inaccurately states that sex differentiation occurs at fertilization.

The biological reality is that development of the testes is determinative of embryonic development to the male or female pathway regardless of chromosomes. The most accurate stages for identifying sex are the second and third trimester, not fertilization.

## **II. Sex Assigned at Birth and Addressing the Biological Reality of Sex**

When a child is born, it is generally assigned to one of two sexes: male or female. Sex designation is required and monitored by the United States Department of Health and Human Services through the Center for Disease Control and Prevention’s National Center for Health Statistics. The National Center for Health Statistics (NCHS) collects statistics pertinent to the health and

wellbeing of all people under United States jurisdiction. In the United States, the legal authority for registering vital statistics, including birth certificates, resides individually with the 50 States, two cities (Washington, DC, and New York City), and five territories (Puerto Rico, the Virgin Islands, Guam, American Samoa, and the Commonwealth of the Northern Mariana Islands).<sup>30</sup> To ensure that vital statistics are properly maintained and consistent the NCHS coordinates collection with state agencies. Since the inception of a national vital statistics system, “the states and the federal government have worked together cooperatively to promote standards and consistency among state vital statistics systems.”<sup>31</sup> To this end, the NCHS produces standard birth certificates as “the principal means of promoting uniformity in the data collected by the states.”<sup>32</sup> United States birth certificates provide three designations: male, female, or not yet determined. If a child’s sex is designated not yet determined, the hospital is instructed that the “[i]tem must be completed. If the record is filled with an N code [not yet determined], send the record to NCHS but query the hospital until a determination of the infant’s sex is made. Send the updated record to NCHS with the updated file.”<sup>33</sup>

Sex designation is made at birth primarily for statistical purposes, but also because traditionally this is when a child’s sex is identified. Sex statistics are used in making pertinent medical, social, and economic decisions. It is with this information that everything from stratification and wage disparities to sex-differentiated disease trajectories can be identified and tracked. Delay in identifying a child’s sex is discouraged both for logistical reasons and because research shows that genital reconstruction is the least biologically traumatizing when done prior to age one.<sup>34</sup>

Most children are designated as either male or female at birth. But, an estimated 1.7% to 4% of children are born Intersex.<sup>35</sup> Intersex is a term referring to a wide variety of individuals who are not easily identifiable as either male or female at birth, including those who have chromosomal abnormalities (such as Klinefelter's syndrome)<sup>36</sup> or ambiguous genitalia.<sup>37</sup> Given the social desire to categorize individuals as either male or female, various policies and approaches have been pursued with the goal of placing an Intersex person into either the female or male category.

This section will explore the various approaches to categorizing Intersex children as either male or female.

### **A. The Potential Need for Perinatal Sex Identification**

Maintaining statistics on sex can be important for addressing sex linked health issues and for tracking sex-based discrimination. Statistical information about sex is important for effective health intervention when there are differences between the sexes in the manifestation of a disease and its treatment. Heart disease is one often-cited health difference between females and males. "The exclusion of females from studies on heart disease is noted as one of the reasons heart disease is often misunderstood for female patients. Until recently, women have been under-represented in many studies that have set the standard for detection and treatment of heart disease. In addition, women with heart disease may have different symptoms than men, and different diagnostic tests may be less accurate in women."<sup>38</sup> Similarly, a Minnesota study on advanced heart failure has indicated that women are typically four years older on diagnosis, compared to their male counterparts.<sup>39</sup> A wide variety of theories exist about the differences in heart disease between the

---

<sup>35</sup> There is some dispute in the medical community about the precise list of conditions that constitute the category of intersex. In addition, the desire to select a sex at birth makes tracking the actual incidence of intersex difficult.

<sup>36</sup> Klinefelter's syndrome is a genetic disorder where a Y chromosome is present and at least one extra X chromosome is present. This is a deviation from the standard human male karyotype where there are only 46 chromosomes and the sex chromosomes are X and Y.

<sup>37</sup> Not all individuals categorized as Intersex have ambiguous genitalia and some conditions leading to categorization as intersex are even difficult to diagnose at birth. For example, Non-classical Adrenal Hyperplasia or Late-onset Congenital Adrenal Hyperplasia often manifests conditions at or after puberty.

sexes including differences in symptoms and physical characteristics of the cardiovascular system.<sup>40</sup>

The National Institutes of Health (NIH) Women's Health Initiative was launched because of "the general underrepresentation of females in health studies and with the goal of providing better and more accurate treatment for females."<sup>41</sup> Determining sex is important for maintaining statistics on health differences between males and females, ensuring that there is equal representation in health studies and ensuring for adequate care when sex differences matter.

Another such sex difference relates to the difference in autism diagnosis for young boys versus girls. Age at autism diagnosis is associated with sex assigned at birth, which causes girls/women with autism to receive a diagnosis later in life or to be "missed" entirely.<sup>42</sup> This trend towards a diagnostic delay for girls/women poses a particularly troubling issue, as later diagnosed individuals demonstrate increased anxiety and depressive symptoms.<sup>43</sup>

Sex identification is also important for monitoring and diagnosing sex-linked genetic disorders. Some genetic disorders are linked to the X chromosome but are recessive, so they only manifest in males. "Examples of such disorders include Duchenne muscular dystrophy and Becker muscular dystrophy (both of which are neuromuscular disorders), fragile X syndrome [(which causes a range of developmental problems including learning disabilities and cognitive impairment)], and some types of leukodystrophy (a group of disorders that affect the central nervous system)."<sup>44</sup> Additionally, there are substantial and pervasive differences in the occurrence and presentation of mental illnesses such as schizophrenia, major depressive disorder, and bipolar disorder between sexes.<sup>45</sup> However,

this may be considered less significant as these disorders are not caused by gender, but rather appear differently related to gender, or, possibly, gender-related socialization. Identifying the sex of the child may lead to faster and more accurate diagnosis of male children and avoid unnecessary testing of female children.

In considering sex discrimination, trends must be identified. Such trends can only be identified among sex groups, because of sex classification. Without having a pool of people designated as male and a separate group designated female, disparate treatments, patterns, and practices could not be addressed. A claim of discrimination may be supported by demonstrating disparate treatment or a pattern or practice of discrimination.<sup>46</sup> A disparate treatment claim cannot be based on statistical differences in treatment between females and males but statistical evidence of an imbalance in treatment may help to establish discriminatory intent.<sup>47</sup> A pattern and practice claim, on the other hand, can be supported by demonstrating statistical imbalance.<sup>48</sup> In a pattern or practice claim “the evidence establishes that the discriminatory actions were the defendant’s regular practice, rather than an isolated instance.”<sup>49</sup> A pattern or practice claim requires statistical support to demonstrate that discrimination is not isolated or motivated by other factors. “A ‘pattern or practice’ means that the defendant has a policy of discriminating, even if the policy is not always followed.”<sup>50</sup> Gross statistical markers of discrimination may be sufficient on their own to demonstrate that discrimination has occurred on its face.<sup>51</sup> To capture whether sex based differences impact employment opportunities or pay, a determination of sex and aggregation of the distinctions in treatment on the basis of sex is necessary.

Finally, our seemingly intractable link between sex and gender makes early identification of sex important to a child’s psychosocial development. Development of gender identity begins before age three.<sup>52</sup> The EO dismisses gender identity as irrelevant to sex and gender differentiation, but scientific and medical evidence has long understood that gender identity plays a critical role. Children early on begin the process of distinguishing genders. The gender cognitive ability of children has already been formed at an

initial level by ages 3-6.<sup>53</sup> “By the age of 2 1/2 or 3 years, most children can answer correctly the question ‘Are you a boy or a girl?’ but it is not until several years later that children attain gender constancy, that is, understand that their sex remains invariant across time and changes in surface appearance (e.g., hair length).”<sup>54</sup> The concept of gender cognition in young children mainly involves children’s understanding of their own and others’ gender identity, gender roles and the gradual formation of gender concepts.<sup>55</sup> The development of a gender identity steadily progresses through early and middle childhood. “It is apparent that by middle childhood children have developed fairly stable conceptions of (a) the degree to which they typify their gender category, (b) their contentedness with their gender assignment, (c) whether they are free to explore cross-sex options or are compelled to conform to gender stereotypes, and (d) whether their own sex is superior to the other.”<sup>56</sup>

The development of gender identity is a critical component in psychosocial development. “These dimensions of gender identity are not strongly related to one another, yet all relate to psychosocial adjustment.”<sup>57</sup> Once children are aware of their gender, they can still borrow from the opposite sex and can more competently relate psychosocially to their peers, since they have a perspective from which to relate. For example, young children may use gender information to infer another child’s toy preferences.<sup>58</sup> In fact, knowledge of a gender identity appears important for self-identity, but gender identity does not lead to total gender role adherence. “It indicates that self-perceptions of gender typicality do not necessarily reflect an unhealthy gender-role straight jacket that undermines

well-being; rather, they appear to contribute positively and directly to a healthy sense of self.”<sup>59</sup>

Pressure to adhere completely to gender lines may be negative. “Clearly, it is felt pressure for gender conformity, not a perception of the self as gender typical, that is harmful.”<sup>60</sup> Gender identity can provide a point of reference for children in developing an identity. Gender identity is about an individual's sense of themselves as male, female, or somewhere along the gender spectrum.<sup>61</sup> Harm occurs when the child no longer can explore their gender identity and is instead pressured or coerced by parents or others to act in a particular gendered manner. For example, young boys may seemingly gravitate towards “masculine” play, such as playing with trucks and horseplay, while young girls may more frequently engage in “feminine” play, such as playing with dolls.<sup>62</sup> However, these tendencies are not inherently sprung from biological differences between genders, but rather are significantly shaped from social cues and feedback that children receive from their social context.<sup>63</sup> “Thus, children’s adjustment is optimized when they (a) are secure in their conceptions of themselves as typical members of their sex yet (b) feel free to explore cross-sex options when they so desire.”<sup>64</sup> Some researchers thus conclude that allowing children to form a gender identity is positive if the child is given some flexibility in adhering to that identity. “Parents and educators might strive to instill in children a sense that they are free to investigate other-sex options, but these adults should also be respectful of children’s need to feel that they are typical and adequate members

of their own gender.”<sup>65</sup> Failing to select a sex, and consequently denying gender identity formation, may result in psychosocial adjustment issues.

One highly publicized attempt at separating sex and gender is the case of Sasha.<sup>66</sup> Sasha was assigned male at birth and not Intersex.<sup>67</sup> Nonetheless, Sasha’s parents decided they did not want to raise him with a gender until they were forced to when he entered school at five years-old.<sup>68</sup> Before this period Sasha’s parents did not use gendered pronouns.<sup>69</sup> They did not reveal their child’s sex to others, including other family members.<sup>70</sup> Sasha’s parents felt that gendering him would preclude him from having more meaningful interactions and force him into materialized, socially constructed versions of his gender.<sup>71</sup>

The intertwined dimorphism of sex and gender is often difficult to tease out from our socialized interaction. Sasha’s parents’ actions betray their own views of gender and their desire to socialize Sasha under their assumptions of proper gender roles. Sasha was allowed to wear any clothing he wanted, “except hyper masculine clothing like shirts with skulls on them.”<sup>72</sup> Sasha was also not allowed to play with Barbie “because yuck, she’s horrible.”<sup>73</sup> His parents also made him wear a girl’s blouse to school with his uniform but not because he chooses to dress that way but instead

because of his parent's gender predilections.<sup>74</sup> "I don't think I'd do it if I thought it was going to make him unhappy, but at the moment he's not really bothered either way. We haven't had any difficult scenarios yet."<sup>75</sup> Sasha's case illustrates the difficulty in living a life devoid of gender identity, in a world where gender roles still matter. The decision to raise Sasha as genderless also worked against the gender identity he was forming as part of his self-identity. Sasha was not allowed to wear the clothing he desired. Instead, those decisions were made for him. He was not allowed to wear certain masculine clothing and was forced to wear feminine clothing. These steps clearly denied Sasha his self-identity. The form of pressure Sasha experienced was not conformity to the aligned sex and gender, but it was pressure nonetheless, specifically pressure not to align his sex and gender.

Denying the existence of gender identity is difficult in a world that is gendered. Sasha's parents illustrate the difficulty in raising a child androgynously when identity and socialization are in part gender linked. It has been posited that sex-typed individuals tend to have gender-polarized thinking, which is often found to reinforce the gender inequality between men and women.<sup>76</sup> Along with this finding, androgynous people have been found to be better adjusted and, therefore, androgyny can be thought of as "a more human standard of psychological health."<sup>77</sup> A more effective manner of challenging gender identity and its link to sex is to allow for gender identity formation and then permitting and encouraging opposite sex behavior or identity when it is desired. Permitting children to form identities that move beyond their initial gender identity is more constructive than establishing pressure against the current gender norms.

Notably, if, as a society, we were able to decouple sex and gender, sex identification at birth would become less significant. Although early sex identification would continue to have health benefits, the statistical needs could be reduced, and the psychosocial needs might be diminished.

## B. The Historical Development of Perinatal Sex Assignment by Physical Attributes

Sex identification is most pressing with children who are born with ambiguous genitalia. It is important to note that both surgical action and inaction are considered controversial and involve long-term risk. It can be argued that irreversible surgical masculinization or feminization may pose long-term harm for the adult that the child must become. Equally, it is proffered that neglecting to intervene surgically commits the child to an existence of harmful genital ambiguity.<sup>78</sup> The first major wave of treatment for children born with ambiguous genitalia involved surgical intervention at or near birth.<sup>79</sup> At this time, surgical intervention was the best practice; this was not challenged until the early 1990s.<sup>80</sup> Under this model, surgical intervention was often dictated by the proximity of the genitalia to the norm.<sup>81</sup> Perceptions of this norm are generally based on the size of clitoris/penis and the desire for alteration to move the genitalia to fit as closely within the norm as possible.<sup>82</sup>

The size of the external genitalia holds some importance. It impacts the ability to engage in penetrative sex after puberty.<sup>83</sup> Another factor in the analysis is the function of the genitalia for urinating.<sup>84</sup> For a male, surgical intervention may be immediately pursued when the urinary tract or the genitalia do not permit standing while urinating. Depending on the size and shape of the external genitalia, a physician would alter the genitalia and

designate the child as either male or female.<sup>85</sup> As an example, surgical intervention that allows a child with ambiguous genitalia to be raised male, may be deemed necessary to enable the child to urinate while standing up. Under these circumstances under the traditional approach, earlier intervention is favored “before the school age, say 5 to 8 years. For psychological reasons it is obviously important that the boy at school should pass urine like his fellows.”<sup>86</sup> In the 1950’s David Innes Williams, considered the “father” of pediatric urology opined that surgical intervention functioned to stop ambiguity of biological sex becoming a “psychological problem,” which equally functioned to bolster the security of the parent–child relationship from anxiety related to this ambiguity.<sup>87</sup> The benefit appears to flow to the parent who may feel anxious about their child’s ambiguity. The biological reality of their genital ambiguity is resolved for the social psychological benefit of adhering to sex dimorphism.

Because a Vaginoplasty is often seen as an easier and more accurate surgery, many children born with ambiguous genitalia are designated female and are surgically altered to have more normal female genitalia.<sup>88</sup> These operations first began before there was wide recognition of Intersex children and the operation was conducted with or without the consent of the parents and it has been generally considered amongst those in the field that the priorities in this intervention are sexual function and psychosocial adjustment.<sup>89</sup> Intervention was seen as prudent by many surgeons to allow a child to live as either a male or female. Surgical intervention at an early age was deemed to limit physical trauma caused by surgery, as well as psycho-social inconsistencies.<sup>90</sup>

<sup>90</sup> Surgical intervention between 6 and 12 months is ideal because it reduces the potential for psychological and social issues such as aggressive or regressive behavior, night terrors, and anxiety. American Academy of Pediatrics, *Timing of Elective Surgery on the Genitalia of Male Children with Particular Reference to the Risks, Benefits, and Psychological Effects of Surgery and Anesthesia*, 97 *PEDIATRICS* 590, 590 (1996).

When greater acknowledgement of Intersex children began in the 1950s, psychologist John Money moved to the forefront in establishing a medical framework for gender development and Intersex treatment.<sup>91</sup> Money recommended early intervention in assigning sex.<sup>92</sup> He indicated that surgeons, with the consent of parents, ought to make a decision as early as possible to intervene and surgically assign a sex at or near birth.<sup>93</sup>

Money had several reasons for arriving at these conclusions. First, Money contended that surgical intervention was necessary to allow a child to obtain gender normalcy.<sup>94</sup> The goal was to provide a clearly “sexed individual” and avoid issues with sex ambiguity.<sup>95</sup> Money argued that gender was more important than sex in healthy psychological interactions.<sup>96</sup> Money felt that parents would bond more quickly and effectively with a child that had a defined sex and gender.<sup>97</sup> In part, Money based his theory on the view that parents had a hard time bonding with a child that has a congenital defect.<sup>98</sup> In addition, Money theorized that a strong gender identity was necessary for healthy psychological development because it allowed for the child to identify with others and explore self-identity.<sup>99</sup> Second, Money contended that gender was socially constructed (not hormonally dependent) and that even surgical alteration of a biological male or female to make him or her a member of the opposite sex could be successful as long as there was sufficient gender normalizing.<sup>100</sup> Third, Money contended that early

intervention facilitated parent child bonding.<sup>101</sup> Money argued that bonding was more effective when parents have a gender identity to socialize toward.<sup>102</sup> Thus, Money argued that a doctor and parent ought to make a decision early on about the preferred sex of the child, conduct an operation to conform the child to that sex, and socialize the child in the gender aligned with the selected sex immediately.<sup>103</sup>

Under this form of treatment, parents are frequently instructed not to reveal intervention or the Intersex status to the child.<sup>104</sup> In fact, diagnoses of this kind were almost never disclosed to the child throughout the 20<sup>th</sup> century.<sup>105</sup> The goal of aligning the child's sex and gender is best met by nondisclosure because "any doubt may undermine development of a gender identity concordant with the assigned sex of rearing."<sup>106</sup> But the failure to disclose their Intersex status to the child complicates a study of Intersex health issues, as it limits the availability of follow-up care.<sup>107</sup>

Early intervention alone is not always sufficient; often, even those with early intervention require further operations or treatment to normalize sex.<sup>108</sup> As the body moves toward and through puberty, various interventions may be necessary to maintain the assigned sex.<sup>109</sup> These interventions may include hormone therapy and other operations to alter physical appearance, such as breast reduction or augmentation. Even with these interventions, some doctors continue to counsel against revealing the child's sex ambiguity and the earlier intervention because the child may not have the cognitive or

psychosocial capabilities to fully comprehend their situation.<sup>110</sup> A recommendation for gradual disclosure with increasing levels of sophistication is recommended to parallel cognitive and psychosocial development.<sup>111</sup>

The success of early intervention is not clear. There are few studies examining the success of socialization and early intervention in the gender and sex identity health of children. There is some evidence that early interventions pose psychological risks for the child as they mature, due in part to their inevitable need for medical follow-up, and the frequent need for surgical revisions later, which has been indicated to lead to the development of psychological distress.<sup>112</sup> In addition, early intervention based on morphological aspects of the genitalia may lead to functional issues (for example, there is evidence that intervention causes significant genital insensitivity)<sup>113</sup> as the child grows and enters puberty. These issues include, but are not limited to, differences between the appearance of the genitalia and their reproductive capacity<sup>114</sup> and the impact of hormone increases at puberty on other aspects of physical appearance.<sup>115</sup>

Further complicating the early intervention socialization model advocated by Money was the 1997 revelation of the failed socialization of David Reimer.<sup>116</sup> Reimer, referred to in medical literature as John, suffered a severe injury to his genitalia as an

<sup>115</sup> Puberty results in the release of hormones that alter physical appearance, in particular secondary sex characteristics. A child assigned a sex opposite of the sex hormones that are released at puberty could see physical changes such as the development of breast tissue or facial hair growth that does not align with their assigned sex.

infant.<sup>117</sup> Reimer's genitalia was altered because doctors determined that the construction of female genitalia would be more successful.<sup>118</sup> Reimer was then raised as a girl.<sup>119</sup> Money traced Reimer's progress.<sup>120</sup> When Reimer turned 10 and hit puberty, Money pronounced Reimer's intervention a success.<sup>121</sup> But later, follow up by journalists and scholars, revealed that Reimer's intervention was unsuccessful.<sup>122</sup> At 16, Reimer decided to live as a man.<sup>123</sup> He explained that he had felt he was a man for years and even had suicidal ideations resulting from these thoughts.<sup>124</sup> Reimer suffered severe long-term psychological effects from this experiment.<sup>125</sup> Reimer and his twin were studied in tandem.<sup>126</sup> The studies included the twins inspecting each other's genitals and simulating sex acts, resulting in both subsequently suffering from mental health issues.<sup>127</sup> Reimer's twin died as the result an overdose of antidepressants in 2002, and Reimer committed suicide in 2004.<sup>128</sup>

Several studies report some number of early intervention patients rejecting their assigned sex.<sup>129</sup> Speculation about the cause of rejection varies. Some researchers contend that there is a

neurobiological connection to gender identity.<sup>130</sup> Other researchers contended that certain Intersex conditions are prone to later rejection<sup>131</sup> while others do not lead to rejection.<sup>132</sup>

Money's early intervention model is notable because, while he acknowledges that gender is socially conditioned, he contends that sex can be altered as long as the conditioned gender is aligned with that sex.<sup>133</sup> This view moves away from the theory that gender is an innate result of the hormones and other biological conditions of sex. Nonetheless, Money's early intervention model pre-supposes the need for sex and gender to be aligned and dimorphic for a person to live a healthy well-adjusted life. Money contends that children are born psychosexually neutral.<sup>134</sup> The physical appearance of a child can be altered and then the gender is determined by rearing. The need to align sex and gender is desirable for the child to feel normal.<sup>135</sup> However, there has been some disagreement on this, as it has also been asserted that early surgical intervention is only ethically supportable when medically indicated as a necessity<sup>136</sup> (for example, when the child is unable to urinate without surgical intervention), which complicates a study of the issue.

The Money model does not move away from the view that sex and gender are connected and dimorphic. Instead, Money and others contend that gender is more important, and sex can be made to align with gender.

First, “gender assignment must be avoided before expert evaluation in newborns.”<sup>142</sup> Expert evaluation requires team intervention: “Ideally, the team includes pediatric subspecialists in endocrinology, surgery, and/or urology, psychology/psychiatry, gynecology, genetics, neonatology, and, if available, social work, nursing, and medical ethics.”<sup>143</sup> The first step rejects surgical intervention on the basis of a physician’s assessment of the physical genitalia alone because it was an inadequate measure of the child’s health and best interests.<sup>144</sup> It also rejects physician intervention at the behest of parents.<sup>145</sup> Instead, the protocol requires expert evaluation of all aspects of the child’s sex.<sup>146</sup> The evaluation includes identification of the Intersex condition, assessment of the potential reproductive health and function of the child, the potential

sexual health of the child, and psychological consequences of intervention, among other things.<sup>147</sup> This approach was intended to be an improvement over previous methodologies that either examined too few dimensions of sex in making an assessment to assign sex or gave too much deference to the parent's desire for an immediate medical resolution.

Second, "evaluation and long-term management must be performed at a center with an experienced multidisciplinary team."<sup>148</sup> A multidisciplinary team can help address all the medical, psychological, and social issues a child and their parents may face.<sup>149</sup> The second step further emphasizes the need to examine potential issues for an Intersex child on the various aspects that may impact health in both the short- and long-term. In addition, the second step requires long-term involvement. Research has indicated that although early intervention was often predicated on the emergency of a child being Intersex and the psychological trauma of sex ambiguity, little continued assistance or monitoring was provided to the parent or the child.<sup>150</sup> In part, the failure to provide continued assistance and intervention was based on the desire to establish the normalcy of the child's assigned sex and gender.<sup>151</sup> Continued medical intervention would imply to the child that there was something wrong with them and doctors wanted to avoid sending that message.<sup>152</sup> Additionally, many doctors believed that surgical intervention was sufficient to resolve the medical crisis and further intervention was unnecessary.<sup>153</sup> The new protocol rejects that view and instead requires continued intervention as vital for the

physical and psychological health of the child and for the management of the parents' relationship with the child.<sup>154</sup> The continued presence of a medical team helps ensure that both parent and child have a healthy and effective approach to a child's status as Intersex.

Third, "all individuals should receive a gender assignment."<sup>155</sup> The protocol does not require immediate intervention at or near birth, although it encourages intervention as early as possible. The Consensus Statement recommends early intervention because "[i]nitial gender uncertainty is unsettling and stressful for families."<sup>156</sup> Children are also less traumatized when surgical intervention occurs early.<sup>157</sup> In addition, early intervention is often necessary for healthy physical development.<sup>158</sup> Even if early surgical intervention is avoided, the new protocol strongly encourages gender assignment. The need for gender assignment is based on a desire to provide healthy psychological development both in bonding with parents and socializing with others.<sup>159</sup> The protocol ascribes significant psychological benefit to gender assignment, even if surgical intervention is postponed.<sup>160</sup> The

<sup>160</sup> Peter A. Lee et al., *Consensus Statement on Management of Intersex Disorders*, 118 PEDIATRICS e488, e490-93 (2006). The Consensus Statement in part focuses on early assignment because gender identity develops early. "Gender identity development begins before the age of 3 years, but the earliest age at which it can be reliably assessed remains unclear. The generalization that the age of 18 months is the upper limit of imposed gender reassignment should be treated with caution and viewed conservatively." *Id.* at e492. The Consensus Statement acknowledges that Intersex children are more prone to "atypical gender role

protocol also presents probability estimates on the success of gender assignment based on Intersex condition.<sup>161</sup> Thus, while it rejects emergency intervention and presents a more holistic approach to assignment than the model advocated by Money and other predecessors, it nonetheless continues to see the vital importance of early assignment of a gender role.

The final two steps place emphasis on the interrelationship between the child and the parents and the need to encourage dialogue and respect the views of the patient and their family. Fourth, “open communication with patients and families is essential, and participation in decision-making is encouraged.”<sup>162</sup> Fifth, “patient and family concerns should be respected and addressed in strict confidence.”<sup>163</sup>

The Consensus Statement and its protocol address advancements in understanding Intersex children and the various conditions that may result in a child being Intersex. The Consensus Statement also takes a more holistic view and provides more options for the child and the parents. Nonetheless, even under the new protocol emphasis is placed on maintaining coherence between gender and sex. The goal remains closely aligning sex and gender to ensure healthy psychological development and social integration.

#### **D. A Potential Delayed Gender Assignment Model**

In response to concerns about sex identification, a new strategy has emerged. Recently, the approach has been to deny any need to assign sex during early childhood development and instead allow the child to make gender decisions as the child matures. Advocates of this model insist that children ought to be given the right to give informed consent about their sex assignment.

The Intersex Society of North America (ISNA) embraces many of the improvements in the treatment of Intersex children

---

behavior” but caution that such behavior is not necessarily indicative of a need to reassign gender or sex. *Id.* The Consensus Statement indicates that if the view is persistent then a specialist should be called in and a reassignment ought to be considered. *Id.*

<sup>161</sup> For example, the Consensus Statements offers that, “More than 90% of patients with XX congenital adrenal hyperplasia and all patients with XY complete androgen insensitivity syndrome assigned female in infancy identify as females.” Peter A. Lee et al., *Consensus Statement on Management of Intersex Disorders*, 118 PEDIATRICS e488, e491 (2006). Given this evidence the Consensus Statement recommends raising children with either of these conditions as female. *Id.*

<sup>162</sup> Peter A. Lee et al., *Consensus Statement on Management of Intersex Disorders*, 118 PEDIATRICS e488, e490 (2006).

under the Consensus Statement.<sup>164</sup> ISNA contends that, although the protocol indicated by the Consensus Statement is a step in the right direction, more emphasis ought to be placed on the decision of the child and that the child's consent is necessary for surgical intervention.<sup>165</sup> Informed consent is advocated to preserve two interests: "bodily integrity and self-determination."<sup>166</sup>

The informed consent model has been embraced by a series of scholars with varying approaches to the decisions as to when or if to designate a sex or gender. Some scholars advocate a child being raised with an Intersex assignment,<sup>167</sup> others advocate that a child should have a fluid assignment elected by the child,<sup>168</sup> others advocate the child have no gender assignment until the child can make an informed decision about the gender assignment,<sup>169</sup> still others advocate a legal mechanism for childhood intervention.<sup>170</sup> Under all of these options the decision for surgical intervention is avoided until puberty, but no consensus about the appropriate approach until surgical intervention has emerged.

Another issue with a consent-based theory on sex and gender selection is that puberty may set in before a child has made a decision about the sex and gender they want to live in. Puberty normally sets in as early as seven for girls and nine for boys.<sup>171</sup> An eight- or nine-year-old may still have difficulty deciding about what sex and gender they would like to live in. Some have advocated the use of puberty delaying medication to stop the onset of puberty until a child decides.<sup>172</sup> But, the use of puberty delaying drugs is controversial. The fact that medical intervention is necessary for a child to be able to have time to select a sex and gender is indicative to some that the decision should be made through the holistic medical-based approach advocated by the Consensus Statement with an emphasis on earlier assignment and intervention. Plus, it is

unclear how long it may take for a child to be secure in deciding about their sex and gender. If eight is not old enough, why would twelve or fourteen be old enough?

Even under a system that embraces consent and advocates for later gender and sex assignment, the focus remains on aligning sex and gender. The choice to delay puberty is based on the increased physical manifestations of sex. The desire is to allow the child to remain in the more sex identity-neutral body that exists before puberty. When puberty occurs, sex identity becomes more central and the congruence between sex and gender is more relevant. Thus, a consent-based model does little to challenge the dimorphic view of sex.

### **III. There is a Long History of Participation by Trans and Intersex Athletes in Women's Sports, and the Rules Regulating Participation are more Permissive and Aligned with Health and Science Evidence over Time**

The concept of “fair play” is invoked in sex segregation because female and male bodies are biologically different. These differences are understood to give a general advantage to male athletes. But the desire to segregate the sexes for competitive sports runs into one significant problem: when athletes do not neatly fit into traditional biological definitions of male or female.

The traditional view of sex segregated sports is that male athletes have a biological competitive advantage over female athletes. This view is rooted in biological generalities of the shape of male and female bodies. Males tend to have “longer arms, bigger and stronger legs, more muscle fiber, ten percent larger hearts and lungs, and stronger and broader shoulders.”<sup>173</sup> Males’ larger hearts result in 16 percent more blood pumped per heartbeat.<sup>174</sup> Larger male lungs result in 25 to 30 percent higher oxygen consumption; elite male athletes have maximum oxygen consumption that is about 10 percent higher than their female counterparts.<sup>175</sup> These attributes tend to give male athletes an advantage in competitions that require pure strength.

These physical differences between males and females are the primary reason there is such concern about male athletes competing in female competitions. The assumption is that these biological differences significantly advantage male athletes. If athletes who have genetic advantages resulting from higher androgen levels are competing with female athletes who do not have

similarly elevated levels of androgens, the view is that the latter will be at a significant disadvantage.

This section explores the history of sex testing in sports, focusing on both Trans and Intersex athletes participating in female competition. By delineating the mechanism and rationale behind sex testing and the history and impact sex testing has had on Trans and Intersex athletes, it is possible to highlight the issues and consequences of sex testing and sex segregated sports. Sex testing illuminates the difficulty in arriving at bright-line rules in distinguishing male from female in certain cases. Sex testing also has the unforeseen consequence of asserting that female athletes are disadvantaged as compared to male athletes.

This section begins by tracing the history of sex testing in international sports. This section then traces the significant events in participation by Trans and Intersex athletes. Finally, this section explores the underlying assumption that female athletes are disadvantaged and why this assumption may be inaccurate.

### **A. The History of Sex Testing in International Sports**

Formalized sex testing in competitive athletic competitions began in the 1960s.<sup>176</sup> The Olympics instituted their first official sex testing practices for the 1968 Games.<sup>177</sup> During the 1968 Olympics, sex testing consisted of a visual inspection of each female athlete to ensure a proper female phenotype.<sup>178</sup> Athletes complained that the test was invasive and degrading.<sup>179</sup> Phenotype testing was imprecise and at times led to inconclusive or erroneous results. Results from genetic studies can be affected by various factors including statistical power, disequilibrium linkage, quality control, confounding and selection bias, as well as real differences from interactions and effect modifiers, which may be informative about

the mechanisms of traits and disease.<sup>180</sup> Phenotype testing was imprecise and at times led to inconclusive or erroneous results.

Both the inaccurate testing and the athletes' privacy concerns led most sporting events to change to a chromosomal test (such as the Barr body test) or a DNA test (such as a polymerase chain reaction test).<sup>181</sup> The most often used test was the Barr body test. The Barr body test detects the presence of two X chromosomes indicating that a person is female or an X and a Y chromosome indicating that a person is a male. The Barr body test has been criticized as leading to the detection of genetic abnormalities that confer no gender related advantage, but which nevertheless sufficiently disqualify and stigmatize an athlete.<sup>182</sup> For example, British geneticist Ferguson-Smith and former British Olympian Elizabeth Ferris posited that the Barr body test barred competitors with androgen insensitivity syndrome, gonadal dysgenesis, Klinefelter syndrome, and mosaicism unfairly.<sup>183</sup>

The International Amateur Athletic Federation (IAAF), the governing body of amateur athletics, officially ceased subjecting all female athletes to sex testing in 1991.<sup>184</sup> DNA testing was again at Lillehammer in 1994 and at Atlanta in 1996, but in view of the strong opposition from medical specialists, the IOC agreed in 1999 to suspend compulsory tests based on sex chromosomes at the 2000 Olympic Games in Sydney.<sup>185</sup> The International Olympic Committee (IOC) officially ceased subjecting all female athletes to sex testing in 2000.<sup>186</sup> Yet, both the IAAF and the IOC continue to subject select individual female athletes to sex testing.<sup>187</sup> The number of individual sex tests conducted is unknown because the IOC and the IAAF attempt to conduct these tests confidentially to

secure the privacy of athletes.<sup>188</sup> This continued ‘private’ testing has equally been criticized, with some asserting that the imposition of sex testing is not made more ethical by increased confidentiality in the practice. In other words, bolstering athletes’ privacy and gender verification practices cannot both be defended by an appeal to fairness.<sup>189</sup>

The individual athlete testing protocol is more elaborate and undertakes to evaluate multiple components of sex in determining the sex of an athlete.<sup>190</sup> Individualized testing can include the use of a gynecologist, endocrinologist, internist, psychologist, and gender expert.<sup>191</sup> The rules first established in 2006 created five categories of athletes eligible to compete in female athletic events.<sup>192</sup>

First, if an athlete is phenotypically and genotypically female.

Second, “if [gender affirming surgery] as well as appropriate hormone replacement therapy are performed before puberty then the athlete is allowed to compete as a female.”<sup>193</sup> The implication is that gender affirming surgery before puberty ensures that a transgender woman does not obtain the advantages associated with a major influx of testosterone during puberty.

Third, “if [gender affirming surgery] is done after puberty then the athlete has to wait two years after gonadectomy before physical and endocrinological evaluation is conducted.”<sup>194</sup> The rationale for this rule is once again centered on the advantage of being exposed to elevated testosterone levels. “The crux of the

This leaves an unspoken sixth class of applicants: those who are determined not to be female and are excluded from completion.

For the 2008 Summer Olympics in Beijing, China, the IOC established a laboratory to conduct sex testing.<sup>200</sup> In 2010 the IOC announced the expansion of the laboratory program and the desire to set up more testing centers.<sup>201</sup> In 2010 the IOC and the IAAF once again revisited the issue of sex testing, given concerns over whether and how to include Intersex athletes with hyperandrogenism.<sup>202</sup> Researchers at King’s College London stated in 2012 that the sex testing policies introduced in time for that summer’s games, were significantly flawed, and urged that their imposition should be withdrawn.<sup>203</sup>

The conferences held to examine this issue resulted in two general conclusions. First, “in order to protect the health of the athlete, sports authorities should have the responsibility to make

sure that any case of female hyperandrogenism that arises under their jurisdiction receives adequate medical follow-up.”<sup>204</sup> Second, rules needed to be put in place to regulate the participation of athletes with hyperandrogenism in competitions for women.”<sup>205</sup> The final rules established for the 2012 Summer Olympics in London, England, held that if competitive advantage (because it is functional and the androgen level is in the male range), the investigated athlete may be declared ineligible to compete in the 2012 [Olympics].”<sup>206</sup>

The conferences dealing with hyperandrogenism led the IOC to reexamine its general rules for sex testing. First, “A female recognized in law should be eligible to compete in female competitions provided that she has androgen levels below the male range . . . or, if within the male range, she has an androgen resistance such that she derives no competitive advantage from their status. Additionally, the rule places the responsibility on legal institutions to make determinations about an athlete’s sex.

Second, all evaluations must be anonymous and, “Should an athlete be considered ineligible to compete, she would be notified of the reasons why, and informed of the conditions she would be required to meet should she wish to become eligible again.”<sup>207</sup> In order to supplement the anonymity required by these evaluations, an anonymous panel would be employed to carry out testing.<sup>208</sup> The second rule presents a possibility for athletes to seek further treatment to reduce competitive advantage and bring them within the eligibility requirement for a female athlete.

Finally, the IOC explained the rationale behind testing protocols. “Although rare, some women develop male-like body characteristics due to an overproduction of male sex hormones, so-called ‘androgens,’ The androgenic effects on the human body explain why men perform better than women in most sports and are, in fact, the very reason for the distinction between male and female

competition in most sports.”<sup>209</sup> The IOC’s policy is entirely dependent on creating a rationale for sex separation where female athletes are protected from competing with “better” male athletes. This rationale has been criticized as being myopic however, as the superiority and dominance of some female athletes is attributed to natural talent when there is an absence of scrutiny over the individual’s gender.<sup>210</sup>

The history of the participation of transgender and intersex athletes illustrates why these changes have occurred and the consequences for Trans and Intersex athletes, as well as female athletes. This section continues by examining the case of Renee Richards and her participation in the U.S. Open Tennis Tournament before examining several high-profile instances involving intersex athletes.

### **1. Game, Set, and Match: Renee Richards and the standard for transgender women participating in women’s sports**

Dr. Renee Richards case is unique because she was the first, and to date only, athlete to obtain a judgment from a US court to compete as a female athlete. The basis for this determination should define our approach to Trans participation in women’s sports. The court’s decision is also illustrative of the concerns underpinning sex testing and its role in sport.

Dr. Renee Richards was born Richard Raskind and assigned male at birth.<sup>211</sup> She had been an ophthalmologist, husband, and father when she underwent a gender affirmingsurgery.<sup>212</sup> Before her surgery she was “an accomplished male tennis player” and ranked 3rd in the East and 13th in the United States overall for men over 35 years old.<sup>213</sup> After her operation Richards wanted to again participate in competitive tennis tournaments, but in the women’s division. Before applying for the 1976 United States Open, Richards entered nine women’s tennis tournaments winning twice and finishing as a runner-up three times.<sup>214</sup>

In 1976 the United States Tennis Association (USTA) and the United States Open Committee (USOC) for the first time implemented the Barr body test (sex-chromatin test) to confirm the sex of female athletes.<sup>215</sup> The Barr body test had been employed by the International Olympic Committee starting in the 1968 Olympics.<sup>216</sup> Both the USTA and the USOC acknowledged that they implemented the Barr body test as a direct result of Richards' application to enter the U.S. Open as a female tennis player.<sup>217</sup> Previously, the U.S. Open only implemented a phenotype test (an observation of primary and secondary sexual characteristics) in establishing the sex of an athlete.<sup>218</sup>

The USTA and the USOC contended the Barr body test was implemented to ensure fairness.<sup>219</sup> Their primary claim was that those who have had gender affirming surgery have a competitive advantage over natural-born female athletes. The advantage is gained from "physical training and development as a male."<sup>220</sup> George E. Gowen of the USTA noted, "We have reason to believe that there are as many as 10,000 transsexuals in the United States and many more female impersonators or imposters. The total number of such persons throughout the world is not known."<sup>221</sup> Gowen indicated that the USTA was concerned about cheating and the use of " 'experiments . . . , to produce athletic stars by means undreamed of a few years ago.' "<sup>222</sup> USTA's apparent concern was over the infusion of male athletes having gender affirming surgery in order to enter into female competitions.<sup>223</sup> The Barr body test would bar those athletes who had undergone gender affirming surgery to maintain "its obligation to assure fairness."<sup>224</sup> It is important to note, however, that this notion has been criticized by experts, due to the belief that this form of testing is ineffective regarding the detection of an unfair athletic advantage.<sup>225</sup>

The USTA and the USOC introduced testimony by Dr. Daniel Federman, professor and chairman of the Department of Medicine at Stanford University, who, in part, testified that the

presence of the Y chromosome provides “physical characteristics in the normal male that affect an individual’s competitive athletic ability.”<sup>226</sup> Federman explained that the Y chromosome and the correspondingly higher levels of androgen (male sex hormones) to estrogen (female sex hormone) result in “greater height, different body proportions, and a higher muscle mass.”<sup>227</sup> He also testified that gender affirming surgery would not impact many of these advantages. “In the adult male beyond puberty, neither the removal of the testes by [gender affirming] surgery, nor any subsequent treatment with estrogen can affect the individual’s achieved height or skeletal structure.”<sup>228</sup> Indeed, gender affirming surgery alone would not reduce male musculature either.<sup>229</sup> “Removal of the testes plus ingestion of estrogens can reduce male strength, but any such effect is partial and depends upon continued ingestion of estrogen to be sustained.”<sup>230</sup> Thus, a transgender woman would still possess the competitive physical attributes of a male and could only hope to reduce male musculature through continued use of estrogen.<sup>231</sup> Federman’s testimony supported the view that transgender women athletes would possess an unfair advantage physically because they retained male physical attributes.<sup>232</sup>

The USTA and the USOC also introduced affidavits from professional female tennis players attesting to the advantage of transgender women in competing against “natural-born” female athletes.<sup>233</sup> Francoise Durr, Janet Newberry, and Kristen K. Shaw each testified that, assuming similar skill levels, a former male has a significant advantage both from being taller and stronger.<sup>234</sup> The position supports the conclusion that inherent height and strength advantage conferred by being born male (or possessing a Y chromosome) can result in competitive advantage.<sup>235</sup> Vicki Berner, Director of Women’s Tennis for the USTA, a former successful professional tennis player, stated, “she was unable to find a record of any woman player over age 40 who has had such a successful competitive record as [Richards], a record unparalleled in the history of women’s professional tennis.”<sup>236</sup> The implication of Berner’s statement is that Richards’ success could only be explained by the

competitive advantage she obtained by being born male.<sup>237</sup> The testimony of these professional tennis players all indicated that Richards had a competitive advantage.

Dr. Roberto Granato, the surgeon who performed Richards' gender affirming surgery, testified that Richards did not possess a competitive advantage over female athletes.<sup>238</sup> Granato testified that the removal of the testes and estrogen therapy reduced androgen levels and decreases muscular mass.<sup>239</sup> Granato also stated that Richards' muscle to fat ratio corresponded to a female body, including breast development.<sup>240</sup> His contention was that Richards' "muscle development, weight, height, and physique fit within the female norm."<sup>241</sup> His ultimate conclusion was that Richards, "should be considered a woman, classified as a female and allowed to compete as such."<sup>242</sup>

Dr. Jon Money, a psychologist and professor practitioner at Johns Hopkins Medical School, whom Richards had consulted, testified that Richards was female and did not have a competitive advantage.<sup>243</sup> Money testified that the Bar body test would have an unjust effect if applied to Richards because all other indicators were that she was female.<sup>244</sup> He explained:

[Dr. Richards] external genital appearance is that of a female; her internal sex is that of a female who has been hysterectomized and ovariectomized; Dr. Richards is psychologically a woman; endrochronologically female; *somatically (muscular tone, height, weight, breasts, physique) Dr. Richards is female and her muscular and fat composition has been transformed to that of a female*; socially Dr. Richards is female; Dr. Richards' gonadal status is that of an ovariectomized female.<sup>245</sup>

Money argued that all of these factors meant that Richards must be recognized as a female "and for anyone in the medical or legal field to find otherwise is completely unjustified."<sup>246</sup> He argued that Richards would "have no unfair advantage when competing against

other women.”<sup>247</sup> This conclusion was based on Richards fitting within the “female norm” for “muscle development, weight, height and physique.”<sup>248</sup>

Finally, Richards introduced the testimony of professional tennis player Billie Jean King who supported Richards’ competing as a female in tennis tournaments.<sup>249</sup> King had participated as a doubles teammate with Richards and had competed in two singles tournaments where Richards also participated.<sup>250</sup> King testified: “[Richards] does not enjoy physical superiority or strength so as to have an advantage over women competitors in the sport of tennis.”<sup>251</sup>

The court ruled in Richards’ favor, deciding that she did not have an advantage over other female athletes and ought to be considered a female and admitted as such in the U.S. Open.<sup>252</sup> The court held, “the requirement of [the USTA and the USOC] that [Richards] pass the Barr body test in order to be eligible to participate in the women’s singles of the U.S. Open is grossly unfair, and violative of her rights under the Human Rights Law of [New York].”<sup>253</sup> But the court did not eliminate the Barr body test as a method of determining sex, “as it appears to be a recognized and acceptable tool for determining sex. However it is not and should not be the sole criterion, whereas here, the circumstances warrant consideration of other factors.”<sup>254</sup> Instead the court noted that “[t]he only justification for using a sex discrimination test in athletic competition is to prevent fraud, i.e. men masquerading as women, competing against women.”<sup>255</sup>

Ultimately, the court did not find justification for precluding Richards because she was advantaged, noting “the unfounded fears and misconceptions of [the USTA and the USOC] must give way to the overwhelming medical evidence that this person is now a female.”<sup>256</sup>

The *Richards* decision represents a significant victory for the recognition of transgender women both in sport and in society. The case remains the only legal decision regarding transgender women participating in sports in their affirmed sex. But Richards’ case also presents a significant problem in the way we conceptualize female athletic competition. The decision was predicated on Richards not

having an advantage over other female competitors. The advantage was her retaining any male characteristics. The court concluded that her competing with other females was appropriate because she no longer possessed those advantages. Her gender affirming surgery and hormone therapy suppressed the benefits of her Y chromosome. The court's reasoning supports the view that femaleness is a disability as compared to maleness. From an athletic standpoint possessing a Y chromosome and obtaining its benefits is an enhancement for a female athlete. It has equally been opined that the complexity and sensitivity of the matter means sports authorities should stop looking for a biological marker to determine the propriety of an athlete's competing. "Instead, we ought to go simply with an athlete's self-identity as a man or woman (only requiring, perhaps, that it be confirmed by her or his legal status)."<sup>257</sup>

Richards has since spoken controversially on the issue, stating that "Having lived for the past 30 years, I know if I'd had surgery at the age of 22, and then at 24 went on the tour, no genetic woman in the world would have been able to come close to me. And so I've reconsidered my opinion."<sup>258</sup> Richards goes further, to insist that being allowed to compete in professional sporting events is something that transgender women cannot expect – bluntly quipping, "that's just life."<sup>259</sup>

After the Richards decision several sports now include transgender women that compete as female athletes. Among those athletes are: Mianne Bagger a Danish born Australian golfer who competes on the Ladies European Tour, Canadian cyclist Kristen Worley, and Canadian mountain biker Michelle Dumaresq.<sup>260</sup> In Mianne Bagger's case, the issue is somewhat fraught, as the Ladies Professional Golf Association (LPGA) had previously amended their membership clause which required that competitors in the ladies category must be assigned female at birth.<sup>261</sup> However, this has lapsed following a decision in late 2024 to update their policy, with the United States Golf Association, along with the LPGA, stating that "Current scientific and medical research shows that sports performance differences exist between biological sexes and such differences begin to occur during the onset of puberty". ## **2. Case studies of Intersex athletes participating in women's sports**

The history of Intersex athletes in the Olympics illustrates the difficulty with sex testing protocols. Often intersex athletes are unaware of their condition and are raised as female. Sex testing can expose their condition to the world and to themselves. In addition, because of changes in sex-testing protocols the timing of an athlete's exposure to testing can often be the difference between being labeled female or male. Finally, while the protocols may change, the focus has always remained on eliminating competitive advantages that intersex athletes may possess.

Stainislawa Walasiewicz, known as Stella Walsh, was a Polish immigrant living in the United States when she competed for Poland in the 1932 and 1936 Summer Olympics.<sup>263</sup> Walsh was a very successful sprinter in the 1930s, setting or matching the 100 meter sprint world record time on six occasions.<sup>264</sup> Her final world record time stood for 11 years.<sup>265</sup> One of her world record times was captured at the 1932 Olympics in Los Angeles, California.<sup>266</sup> Four years later in Berlin she attempted to duplicate her feat.<sup>267</sup> Instead, she was defeated by United States sprinter Helen Stephens.<sup>268</sup> Polish media questioned the victory claiming that Stephens was male and

In December 1980, Stella Walsh was shot and killed during a robbery in Cleveland, Ohio.<sup>271</sup> During her autopsy the coroner, Samuel Gerber, discovered that Walsh "had no internal female reproductive organs, and possessed an underdeveloped and non-functioning penis, 'masculine' breasts and an abnormal urinary opening."<sup>272</sup> Gerber determined that Walsh's sex was "likely ambiguous at birth" and that her parents chose to raise her as a girl.<sup>273</sup> Gerber concluded, "Walsh 'lived and died a female . . . . Socially, culturally and legally, Stella Walsh was accepted as female for 69 years."<sup>274</sup> Walsh, in fact, had "mosaicism, a mutation that causes some cells to be XY and others to be XX."<sup>275</sup> The IOC decided not to strip Walsh of her medals.

The most recent sex testing controversy surrounds South African middle distance runner Caster Semenya.<sup>340</sup> Semenya made her international debut at the 2008 World Junior Championships in Poland.<sup>341</sup> At the 2008 Commonwealth Youth Games she won gold in the 800 meters.<sup>342</sup> At the 2009 African Junior Championships she won gold in both the 800 and 1,500 meters.<sup>343</sup> Her 800 meter time set a junior national record, a meet record, and was the fastest time by a female athlete at that stage of the 2009 track season.<sup>344</sup> Semenya's time qualified her for the 2009 World Championship in Berlin, Germany.<sup>345</sup> She took gold at the World Championship and improved on her earlier time.<sup>346</sup>

Citing the drastic improvements in Semenya's times between the 2008 and 2009 track season, the IAAF launched an investigation.<sup>347</sup> She was subjected to both drug and sex testing.<sup>348</sup>

In November 2009, the IAAF announced that Semenya was still undergoing testing to determine her eligibility.<sup>349</sup> In March 2010, the IAAF announced that no further progress had been made in Semenya's case.<sup>350</sup> Later in the same month, Semenya announced her intention to return to competition, she confirmed her commitment in June indicating that she was neither banned nor declared ineligible.<sup>351</sup> In July 2010, the IAAF announced that Semenya was eligible to compete.<sup>352</sup>

The IAAF attempts to keep sex testing confidential and has not made any official announcement about Semenya's diagnosis.<sup>353</sup> Reports indicated that Semenya likely had an intersex condition including the presence of internal testes and male reproductive organs.<sup>354</sup> The length of the delay in announcing her ability to compete is also assumed to correspond to increased levels of androgens and testosterone in her system.<sup>355</sup> Her eligibility determination is linked either to treatment to reduce the advantage she gained from her intersex condition or a determination that she gained no advantage from the condition.<sup>356</sup> The Court of Arbitration for Sports held that Caster Semenya, under an IAAF regulation, would be required to take testosterone suppressants in order to compete in the women's division. Due in part to Semenya's case the IAAF launched further meetings to discuss sex testing practices and specifically to focus on the inclusion of athletes with hyperandrogenism.<sup>357</sup>

This is not an exhaustive list of female athletes who have either been identified as intersex or failed sex testing in some other fashion. Part of the reason this list is incomplete is that the IAAF attempts to maintain the privacy of athletes, and test results are often not released. Nonetheless, there are indications that during the 1972, 1976, and 1984 Olympics nine athletes were determined to be ineligible as a result of sex testing.<sup>358</sup> During the 1996 Summer Olympics in Atlanta eight athletes failed sex testing.<sup>359</sup> Reports indicate that of the eight, seven had Androgen Insensitivity Disorder, and the eighth had 5-alpha-reductase deficiency.<sup>360</sup> All eight were allowed to compete.<sup>361</sup>

These vignettes illustrate the difficulty in making sex determinations for female athletes. They also highlight the human element involved in these cases. In the majority of cases the women who are sex tested and found to be intersex had no idea of their condition. The results were as much a surprise to them as they were to the officials conducting the tests. Athletic competitions are concerned about the advantage that intersex athletes may have over other female athletes. It is under the banner of fairness that sex testing policies are enacted.

### **B. The Assumptions in Sex Testing Female Athletes and Why they may be Inaccurate**

Sex segregation in sport is based on the assumption that males have more athletic bodies. The larger skeletal frame, muscle mass, lungs, and heart provide males with greater strength. Greater strength results in a competitive advantage for male athletes.

The views expressed by the *Richards* court and the various rules established by the IAAF and the IOC focus on eliminating this advantage. The inherent assumption in this view is that the female athlete is disabled or disadvantage as compared to the male athlete and the Trans and Intersex athlete who possess elevated levels of androgens or some other advantage conferred by the presence of a male chromosome. This does not discount the very real benefit of the expanded view of sex exemplified by the *Richards* court, nor the attempts by the IAAF and the IOC to be more inclusive over the

years. It rather forms the covert premise that underlies the rules that govern female sports. In fact, there is no sex testing in male sports, because the assumption is that if a female were to participate, she would possess no genetic advantage.

But a straight comparison between the biological differences between males and females paints an incomplete picture of the dynamic of competitive sports. First, it inherently ignores some of the advantages that female athletes may have over male athletes. Second, it ignores the role that social and economic conditions play in the development of sports.

### **1. The biological advantages of female athletes**

The first major assumption that is ignored in sex testing's assumption that male athletes are biologically advantaged is that female athletes also possess biological advantages. Female athletes' burn fat at a higher ratio to carbohydrates than male athletes during endurance exercises.<sup>362</sup> Burning more fat and less carbohydrates is a more efficient use of energy and provides a marked endurance advantage for female athletes.<sup>363</sup> Females also possess more uniformly distributed and efficient sweat glands; helping both with endurance and energy efficiency.<sup>364</sup> While females tend to weigh less, they have a higher percentage of body fat.<sup>365</sup> A study on intersexual differences within rock-climbing gleaned interesting results regarding the perceived gulf between gender and specific muscle strength, showing in part that there are non-existing or negligible gender differences of specific muscle strength.<sup>366 367</sup>

Body fat distribution also makes women more buoyant and thus more efficient swimmers, in particular over<sup>368369</sup>

The composition of female bodies establishes some advantages in endurance capabilities. The distribution of sweat glands, the more efficient use of fat and carbohydrates, and the distribution of fat make females more efficient endurance athletes. Interestingly, it has been demonstrated that within ultra-marathon races, the performance gap between sexes reduced with age; elderly female ultra-marathoners (those of 75 years and older) displayed a performance difference of less than 4% compared to male ultra-marathoners.<sup>370</sup> This raises the question of whether the supposed gender advantage of males is truthfully less tenuous than is purported, or whether elderly female ultra-marathoners are more individually selected for their exceptional performance.

In competitive ultra-marathon races females fatigue less quickly than males providing them with a distinct biological advantage.<sup>371</sup> Ultra-marathon runners like Laura McDonough, Rhonda Provost, Pam Reed, and Ann Trason have on several occasions beaten similarly trained men in ultra-marathon races sometimes by hours.<sup>372</sup> Courtney Dauwalter won the Moab 240 ultra-marathon by 10 hours over male and female athletes.

Similarly, in the endurance event of ultra-cycling, female racers are competitive with male racers. Seana Hogan, for example, has been competitive with male racers in various ultra-cycling events and on several occasions has beaten male competitors and set race records.<sup>373</sup> Fiona Kolbinger beat male and female athletes in

Two women have won the Iditarod Trail Sled Dog Race.<sup>374</sup> Libby Riddles won in 1985, and Susan Butcher won four times between 1986 and 1990, including three consecutive races.<sup>375</sup> Butcher is one of only six people to win the Iditarod at least four times.<sup>376</sup>

In addition to endurance benefits, female athletes' fat distribution makes them more efficient distance swimmers.<sup>377</sup> Female athletes are routinely faster than male athletes in open water distance swims and their advantage increases as the distance increases.<sup>378</sup> Between 1900 to 2010, in English Channel swim times women regularly performed equal to or better than men.<sup>379</sup> Additionally, the typically shorter limbs of women have been found to result in a more horizontal and streamlined position in the water,<sup>380</sup> making them more efficient performers. In open-water long-distance swimming events that make up the "Triple Crown of Open Water Swimming" which includes the "Catalina Channel Swim," the "English Channel Swim" and the "Manhattan Island Marathon Swim," women were about 0.06 km/h (0.037 mph) faster than men<sup>381 382</sup>

In the 10-meter air rifle - the current world records in the qualification rounds as well as finals for women (634 and 252.9 respectively) are higher than those for men (633.5 and 252.8).

Other sports that segregate between female and male athletes focus on the differences in biology. The quintessential example is artistic gymnastics. The two competitions only share two events, the vault and the floor exercise. Females additionally participate in balance beam and uneven bars. Males compete in the pommel horse,

high bar, parallel bars, and the still rings. The male events place a greater emphasis on upper body strength, an area where biological factors benefit male athletes. The balance beam advantages a lower center of gravity and the nimbleness that corresponds to smaller body size. The uneven bars are designed to require the athlete to travel from a lower to a higher bar. The position of the bar and the need to travel between the two bars is advantageous to smaller athletes.

The differences in competitive achievement between male and female athletes may have less to do with the advantages of male athletes and more to do with having more sports that prize the athletic advantages that males possess. If sports were instead focused on the advantages of female athletes, female athletes would (and sometimes do) outperform males. Fostering an environment that prizes female athletic advantages may even eliminate the need for sex comparison and reduce the tension over participation by Trans or Intersex athletes.

## **2. The impact of social and economic conditions on female athletes**

At the start of the modern Olympics in 1896 female athletes were excluded. Pierre de Coubertin, the founder of the modern Olympics, explained that female participation would be, “impractical, uninteresting, unaesthetic, and incorrect.”<sup>383</sup>

Female athletes began limited participation at the 1900 Olympics in Paris, France.<sup>384</sup> More significant participation by female athletes did not begin until the 1930s.<sup>385</sup> During this early period female athletic participation was generally discouraged because sports were thought to be too violent.<sup>386</sup> The medical community even indicated that participation was bad for reproductive health.<sup>387</sup> Criticism of female participation in sports often centered on the erosion of femininity associated with athletic bodies.<sup>388</sup> With this in mind, it appears that gender equality in sports cannot be separated from gender equality in the sociocultural sector, and it is therefore necessary to invest economically and take

proactive measures to achieve real equity, both in the social and sports contexts alike.

Participation by female athletes increased markedly in the United States with the passage of Title IX of the Education Amendments of 1972.<sup>389</sup> Title IX established, “No person in the United States shall, on the basis of sex, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any education program or activity receiving federal financial assistance.”<sup>390</sup> Title IX required schools to provide equal opportunities for athletic participation for both female and male athletes. The result was a significant increase in the female athletic opportunities in schools from primary through post-secondary. Despite the increased opportunities for female athletes, many of the social attitudes against female participation in sport have been slow to change.<sup>391</sup> For example of this, it has been determined that women were four times more likely than men to report that their gender or sexual orientation influenced their opportunities in elite sport.<sup>392</sup>

Unfortunately, Title IX does not require equal funding for college athletes. The 2021 NCAA men’s and women’s basketball tournament was held in the same location due to the Corona Virus. The event gained viral attention when participants in the women’s tournament posted pictures on social media showing the stark disparities in exercise facilities for men and women, who were separated by a curtain. The men had full gym with multiple sets of various weight and exercise equipment. The women had a set of dumbbells. After the social media backlash, the NCAA commissioned an external report on the disparities between the two events. The NCAA External Gender Equity Review determined that during the 2019 NCAA men’s and women’s basketball tournaments there was a \$35 million funding gap.

NCAA women’s basketball continues to grow in viewership. ESPN reported that the 2022-23 National Championship was viewed by 9.9 million Americans and the Final Four was viewed by an average of 6.5 million, both records.

An analysis of total expenses indicates that Division I athletics departments are generally spending twice as much on their

men's programs than on their women's programs. The largest gap in spending occurs at the Football Bowl Subdivision level.

Title IX revolutionized opportunities for female participation in amateur sports, but there has yet to be similar opportunities for professional female athletes. The longest lasting professional organization for female athletes is the Women's National Basketball Association. Although the WNBA provides opportunities for female athletes to participate in professional basketball, the pay for WNBA players is significantly lower than their male counterparts.

The median salary for an NBA player is \$2.5 million.<sup>393</sup> The minimum salary for an NBA player is \$473,604.<sup>394</sup> The salary cap for a team of 11 WNBA players is \$878,000.<sup>395</sup> There may be a myriad of reasons for the discrepancy that range from the profitability of the two leagues to their age (the NBA has been around for 50 more years). The point remains that there are fewer opportunities for female athletes and fewer incentives to participate even when those opportunities exist. The incentive to put in the time and effort necessary to become a professional athlete is far higher for male athletes than for female athletes because they can obtain significantly higher salaries.<sup>396</sup>

NBA players currently receive approximately 50% of shared revenue with owners, while WNBA players receive only 20%. WNBA salaries range from \$62,285 to \$234,936. NBA salaries range from \$1,017,781 to \$48,070,014. The NBA salary cap is \$156.98 million, while the WNBA salary cap is \$1.34 million.

The disparity in WNBA and NBA salaries resulted in many WNBA players playing in the Russian league during the offseason. The most profound result of these financial decisions was the arrest of WNBA superstar Brittney Griner for allegedly possessing a vape pen containing marijuana. Griner spent significant time in a Russian prison before President Joe Biden secured her release.

The social and economic conditions associated with female participation in athletics impacts the success of female athletes. Female athletes have participated in organized sports for far fewer

years than their male counterparts. Female athletes have fewer opportunities to participate in professional sports. Even when those opportunities exist, they are often paid less. The result is fewer opportunities and fewer incentives for females who do participate in sports, to take the time and training to attain the same athletic performance of male athletes. When younger females are presented with the opportunity to participate in sports they may not have the same level of desire to play at an elite level as males. A study of the promotion of female sports in Switzerland concluded that specific bodies for the promotion of women and girls should be provided with sufficient financial and human resources to have impact beyond visibility<sup>397</sup>. This same study indicated that attempts to redistribute resources more equally has barring impacts on funding opportunities, underlining the notion that a several-pronged approach considering external pressures, steering impulses and organizational goals are necessary in order to ensure the successful promotion of women and girls in organized sport. The social and economic realities of female sports may be in part responsible for the relative underperformance of female athlete as compared to male athletes.

Sex testing in sports is primarily directed at ensuring fair play and eliminating any advantages that certain female athletes or male athletes masquerading as females may have in participating in female athletic events. The push for fairness has resulted in two unforeseen consequences. First, many Trans and Intersex athletes have been excluded from participating in female sports even though they were considered female in other aspects of life. The sports community has taken steps to attempt to broaden participation by recognizing that some Intersex and Trans athletes may not possess advantages associated with male biology. Nonetheless, certain Intersex and Trans athletes are still excluded because they are perceived to possess those advantages. The persistent view about these advantages leads to the second consequence. Female athletes under this mechanism are treated as disadvantaged or less-than male athletes. This view is problematic for two reasons: (1) female athletes do have some physical advantages over male athletes, but most sports prize male athletic ability, and (2) social and economic conditions have created decades of advantages for male athletes that are not present for female athletes. The presence of Trans and Intersex athletes highlights these two issues and further illustrates the problems with perceptions of sex as fixed and divided.

#### **IV. Conclusion**

The Executive Order on “Defending Women from Gender Ideology Extremism and Restoring Biological Truth to the Federal Government” asserts the reality of biological sex is easy and straight forward. It asserts a simplistic, binary stance: at conception men have a small reproductive cell, and women have a large reproductive cell. The size of the reproductive cell establishes your sex and gender as dimorphic and immutable. Under this view, gender identity is not part of biological reality and is irrelevant to sex or gender. Examination of scientific and medical evidence reveals, however, that the actual biological reality of sex cannot be determined at fertilization and even in embryonic and fetal growth it involves “[a] bewildering number of hormones and growth factors.” Gender identity is part of the biological reality of sex and has been identified as playing an important role in medical and scientific journals and practice for decades. Far from being straightforward, sex is a complicated set of factors most of which are not immutable. Denying the actual biological reality of sex for an allegedly simple rule not only denies the scientific and medical reality but also peoples lived experiences.
